

Package: gdistance (via r-universe)

October 30, 2024

Type Package

Title Distances and Routes on Geographical Grids

Version 1.6.4

URL <https://AgrDataSci.github.io/gdistance/>

BugReports <https://github.com/AgrDataSci/gdistance/issues>

Description Provides classes and functions to calculate various distance measures and routes in heterogeneous geographic spaces represented as grids. The package implements measures to model dispersal histories first presented by van Etten and Hijmans (2010) <[doi:10.1371/journal.pone.0012060](https://doi.org/10.1371/journal.pone.0012060)>. Least-cost distances as well as more complex distances based on (constrained) random walks can be calculated. The distances implemented in the package are used in geographical genetics, accessibility indicators, and may also have applications in other fields of geospatial analysis.

accCost	<i>Accumulated Cost Surface</i>
---------	---------------------------------

Description

Calculates the accumulated cost surface from one or more origins.

Usage

```
accCost(x, fromCoords)
```

Arguments

x	object of class TransitionLayer
fromCoords	origin point locations (SpatialPoints, matrix or numeric class)

Details

If more than one coordinate is supplied in fromCoords, the function calculates the minimum least-cost distance from any origin point.

The function uses Dijkstra's algorithm (as implemented in the igraph package).

Value

a RasterLayer object

Author(s)

Jacob van Etten

References

c2 <- c(1.5,5.5)

A <- accCost(tr, c1)
plot(A)
text(A)
```

adjacencyFromTransition

Adjacent cells

Description

Identify pairs of cells that are adjacent.

Usage

```
adjacencyFromTransition(x)
```

Arguments

x TransitionLayer

Details

Extracts the indices of those cells that are connected (e.g. cells i,j that have a non-zero value in the transition matrix).

Cell numbers are unique indices of cells in the original grid. By convention, cell numbers start with 1 in the upper-left corner of the grid and increase from left to right and from top to bottom.

Value

A two column matrix with each row containing a pair of adjacent cells.

Examples

```
library("raster")
r <- raster(nrows = 6, ncols = 7,
            xmn = 0, xmx = 7,
            ymn = 0, ymx = 6,
            crs = "+proj=utm +units=m")
r[] <- runif(6 * 7)
tr <- transition(r, function(x) 1 / mean(x), 8)

aft <- adjacencyFromTransition(tr)

head(aft)
```

ArithMath-methods	<i>Arithmetic and mathematical operations with objects of Transition* classes</i>
-------------------	---

Description

Standard arithmetic operators for computations with Transition* objects and numeric values. Transition objects must have the same extent and resolution. All arithmetic and mathematical operations that work on the sparse matrices are available for Transition* objects.

Usage

```
## S4 method for signature 'TransitionLayer,TransitionLayer'  
Arith(e1, e2)
```

Arguments

e1	objects
e2	objects

Value

a Transition* object or numeric.

Author(s)

Jacob van Etten

Examples

```
#create a new raster and set all its values to unity.  
raster <- raster(nrows=18, ncols=36)  
raster <- setValues(raster,rep(1,ncell(raster)))  
  
#create TransitionLayer objects  
tr1 <- transition(raster,mean,4)  
tr2 <- tr1  
  
#arithmetic operations  
tr3 <- tr1 * tr2  
tr4 <- tr3 * 4  
  
#mathematical operations  
tr5 <- sqrt(tr4)
```

commuteDistance	<i>Commuter-time distance</i>
-----------------	-------------------------------

Description

Calculates the resistance distance between points.

Usage

```
commuteDistance(x, coords)
```

Arguments

x	object of class TransitionLayer
coords	point locations coordinates (of SpatialPoints, matrix or numeric class)

Details

This function calculates the expected random-walk commute time between nodes in a graph. It is defined as the effective distance (resistance distance) between the selected nodes multiplied by the volume of the graph, which is the sum of the conductance weights of all the edges in the graph (Chandra et al. 1997). The result represents the average number of steps that is needed to commute between the nodes during a random walk.

The function implements the algorithm given by Fouss et al. (2007).

Before calculating commute-time distances from a TransitionLayer object, see if you need to apply the function [geoCorrection](#)

Value

distance matrix (S3 class dist or matrix)

Author(s)

Jacob van Etten

```
library("raster")
# Create a new raster and set all its values to unity.
r <- raster(nrows=18, ncols=36)
r <- setValues(r,rep(1,ncell(raster)))

#Create a Transition object from the raster
tr <- transition(r, function(x) 1/mean(x),4)

# Create two sets of coordinates
library("sp")
sP1 <- SpatialPoints(cbind(c(65,5,-65),c(55,35,-35)))
sP2 <- SpatialPoints(cbind(c(50,15,-40),c(80,20,-5)))

#Calculate the resistance distance between the points
commuteDistance(tr, sP1)
```

Coords class

Coords class

Description

This is a class union, providing a convenient class for coordinates in several formats.

Details

The class accepts coordinates in any of the following formats: 1. SpatialPoints 2. two-columned matrix 3. vector of length 2

Examples

```
showClass("Coords")
```

`costDistance`*Cost distance*

Description

Calculate the least-cost distance between points.

Usage

```
costDistance(x, fromCoords, toCoords)
```

Arguments

<code>x</code>	object of class <code>TransitionLayer</code>
<code>fromCoords</code>	first set of point locations (of <code>SpatialPoints</code> , matrix or numeric class)
<code>toCoords</code>	optional, second set of point locations (of <code>SpatialPoints</code> , matrix or numeric class)

Details

Cost units between cells are defined as the reciprocal of the values in the transition matrix.

The function uses Dijkstra's algorithm, as implemented in the `igraph` package.

A projection correction is needed for accuracy in the case of grid data for a longlat raster (see function `geoCorrection`).

Value

distance matrix (S3 class `dist` or matrix)

Author(s)

Jacob van Etten

genDist	<i>Genetic distances and coordinates of haplogroup R1b1b2 populations in Europe</i>
---------	---

Description

genDist: Genetic distances between 23 populations of Y-chromosome haplogroup R1b1b2 in Europe, calculated from haplotype microsatellite data (see source).

Format

dist object (genDist) and data.frame (popCoord)

Details

The distance measure used is the negative logarithm of the shared proportion of alleles.

popCoord: Geographic coordinates of the same populations.

Source

Distances calculated from Table S1 in Balaesque et al. (2010). Coordinates from Table 1.

geoCorrection	<i>Geographic Correction</i>
---------------	------------------------------

Description

Correct 'TransitionLayer' objects taking into account local distances

Usage

```
geoCorrection(x, type, ...)
```

Arguments

x	object of class Transition*
type	type of correction: "c", "r", or missing (only required for lonlat, see Details)
...	additional arguments passed to methods. <code>multpl</code> with correction factor (TRUE) or corrected values (FALSE, the default). <code>sc1</code> scale the correction values (default is FALSE)

Details

Geographic correction is necessary for all objects of the class Transition that are either: (1) based on a grid in a geographic (lonlat) projection and covering a large area; (2) made with directions > 4. The function will correct for map distortion, as well as for diagonal connections between grid cells (which cover a longer distance than vertical or horizontal connections).

When working with lonlat grids, users should also anticipate whether they will use methods based on either least-cost or random walks, and set the `type` argument accordingly. In the case of least-cost distances, the correction is only done in East-West direction. In the case of random walks there should be an additional correction which reduces the conductance in North-South direction (`type="r"`).

The correction is done by dividing conductance values by the inter-cell distance. Distances are calculated as great-circle distances for lonlat grids (see function `[raster]{isLonLat}`) and Euclidean distances for all other grids.

In the case of randomised shortest paths, the need for correction is somewhat in between these two correction methods. We have not developed an analytical solution for this problem yet. With very low values for theta, you may choose the correction for random walks, and for high values the one for least-cost paths. Users who want to work with intermediate values of theta are encouraged to experiment with different solutions.

The values are scaled to get values near 1 if the argument `sc1` is set to TRUE. This is desirable for subsequent calculations involving random walk calculations. Values are divided by the W-E inter-cell distance (at the centre of the grid).

Value

a 'Transition*' object

Author(s)

Jacob van Etten

Examples

```
library("raster")
r <- raster(ncol=36,nrow=18)
r <- setValues(r,rep(1,times=ncell(r)))
tr <- transition(r, mean, directions=8)

# directly
tr1 <- geoCorrection(tr, type="c", multpl=FALSE)
```

```
tr1

# the same, but with a separate correction matrix
trCorr <- geoCorrection(tr, type="c", multpl=TRUE)
tr2 <- tr * trCorr
tr2
```

normalize

Normalize

Description

Normalize the transition matrix.

Usage

```
normalize(x, ...)
```

Arguments

x object of class Transition*
... optional argument method (see Details)

Details

argument method passed through ... a character for the normalization method the default is 'row' users can set the optional method argument to either "col" or "symm"

Normalization of the weighted adjacency matrix in the Transition* object. Matrix values are divided by their respective row-sums, column-sums, or the product of the square-roots of both (symmetric normalization).

The default method is row-normalization. To use the other normalization methods, users can set the optional method argument to either "col" or "symm".

For random walk calculations a symmetric matrix is needed (method = "symm").

Value

an object of class TransitionLayer

Author(s)

Jacob van Etten

References

von Luxburg, U. 2007. A tutorial on spectral clustering. *Statistics and Computing* 17(4), 395-416. doi:10.1007/s112220079033z

Chung, F. 1997. *Spectral Graph Theory*. Conference Board of the Mathematical Sciences, Washington.

Examples

```
library("raster")
r <- raster(ncol=36,nrow=18)
r <- setValues(r,rep(1,times=ncell(r)))
tr <- transition(r, mean, directions=8)

normalize(tr)

normalize(tr, method="symm")
```

overlap

Overlap and nonoverlap of trajectories

Description

Special functions to calculate the degree of overlap and nonoverlap between trajectories

Usage

```
overlap(a, b)
```

Arguments

a	matrix object
b	matrix object

Details

These functions are used by the pathInc() as defaults.

Value

A matrix object

Note

The functions are provided here to assist the user in defining alternative measures of overlap / nonoverlap.

Author(s)

Jacob van Etten

 passage

Probability of passage

Description

Calculates for each cell the number of passages of a random-walk or randomised shortest paths with given origin(s) and destination(s). Either the total or the net number of passages can be calculated. In the case of multiple origins or destinations, each receives equal weight.

Usage

```
passage(x, origin, goal, theta, ...)
```

Arguments

x	Object of class Transition*
origin	SpatialPoints, matrix or numeric object with coordinates or RasterLayer object with origin cells set to TRUE
goal	SpatialPoints, matrix or numeric object with coordinates or RasterLayer object with origin cells set to TRUE
theta	If zero or missing, a random walk results. If a numeric value $0 < \theta < 20$ is given, randomised shortest paths are calculated; theta is the degree from which the path randomly deviates from the shortest path
...	Additional arguments: totalNet ("total" or "net"), and output ("RasterLayer" or "Transition")

Details

The net number of passages between i and j is defined as: $\text{abs}(\text{passages from i to j} - \text{passages from j to i})$.

Defaults for additional argument totalNet is "net" and for output it is "RasterLayer".

Random walk requires a symmetric transition matrix.

Value

RasterLayer or Transition object, depending on the output argument

 pathInc

Incidence of paths from a common origin: overlap and non-overlap

Description

Calculate the overlap and non-overlap of paths departing from a common origin. Two algorithms are available: random walk and randomised shortest paths.

Usage

```
pathInc(x, origin, from, to, theta, weight, ...)
```

Arguments

x	transition matrix of class Transition*
origin	coordinates of the origin (one point location, SpatialPoints, matrix or numeric class)
from	coordinates of the destinations (SpatialPoints, matrix or numeric class)
to	second set of coordinates of the destinations (can be missing)
theta	value > 0 and < 20 (randomised shortest paths) or missing (random walk)
weight	matrix – Reciprocals of the non-zero values are used as weights. If missing, reciprocals of the transition matrix are used.
...	additional arguments passed to methods. See Details.

Details

This is a complex wrapper function that calculates to what extent dispersal routes overlap or do not overlap.

First, the function calculates the trajectories for all "from" and "to" locations, starting from a single "origin" location. These trajectories can either be based on random walks or randomised shortest paths (giving a value to theta).

Then, for all unique pairs of trajectories, it calculates the extent to which these trajectories overlap or diverge. These values are given back to the user as a list of (distance) matrices.

If only "from" coordinates are given, the function calculates symmetric distance matrices for all combinations of points in "from". If both "from" and "to" coordinates are given, the function calculates a matrix of values with rows for all locations in "from" and columns for all locations in "to".

Overlap is currently calculated as the minimum values of each pair of trajectories compared. Non-overlap uses the following formula: $\text{Nonoverlap} = \max(0, \max(a,b) * (1 - \min(a,b)) - \min(a,b))$ (see van Etten and Hijmans 2010). See the last example to learn how to use an alternative function.

Value

list of dist objects or list of matrices

```
library("raster")
library("sp")

# Create TransitionLayer
r <- raster(ncol=36,nrow=18)
r <- setValues(r,rep(1,times=ncell(r)))
tr <- transition(r,mean,directions=4)

# Two different types of correction are required
trR <- geoCorrection(tr, type="r", multpl=FALSE)
trC <- geoCorrection(tr, type="c", multpl=FALSE)

# Create TransitionStack
ts <- stack(trR, trR)

# Points for origin and coordinates between which to calculate path (non)overlaps
sP0 <- SpatialPoints(cbind(0,0))
sP1 <- SpatialPoints(cbind(c(65,5,-65),c(-55,35,-35)))

# Randomised shortest paths
# rescaling is needed: exp(-theta * trC) should give reasonable values
# divide by median of the non-zero values
trC <- trC / median(transitionMatrix(trC)@x)
pathInc(trC, origin=sP0, from=sP1, theta=2)

# Random walk
pathInc(trR, origin=sP0, from=sP1)

# TransitionStack as weights
pathInc(trR, origin=sP0, from=sP1, weight=ts)

# Demonstrate use of an alternative function
#The current default is to take the minimum of each pair of layers

altoverlap <- function(a, b)
{
```

```

aV <- as.vector(a[,rep(1:ncol(a), each=ncol(b))])
bV <- as.vector(b[,rep(1:ncol(b), times=ncol(a))])
result <- matrix(aV * bV, nrow = nrow(a), ncol=ncol(a)*ncol(b))
return(result)
}

pathInc(trR, origin=sP0, from=sP1, weight=ts, functions=list(altoverlap))

```

raster,TransitionLayer-method

RasterLayer from TransitionLayer object

Description

Create a RasterLayer from a TransitionLayer with a call to the generic function raster. The $n \times n$ transition matrix of the TransitionLayer is transformed to form the values n cells of a raster.

Usage

```

## S4 method for signature 'TransitionLayer'
raster(x, reduceMethod = "NZcolMeans")

```

Arguments

x an object of class Transition*

reduceMethod character for the method to reduce the transition matrix. See details

Details

The following methods to 'reduce' the transition matrix are available with the optional argument reduceMethod):

- colSums
- rowSums
- colMeans
- rowMeans
- NZcolMeans
- NZrowMeans

The latter two methods only take into account the non-zero entries in the transition matrix. The default is NZcolMeans.

Value

a RasterLayer

Author(s)

Jacob van Etten

Examples

```
#create a new raster and set all its values to unity.
r <- raster(nrows=18, ncols=36)
r <- setValues(r,runif(ncell(r),0,1))

#create a Transition object from the raster
tr1 <- transition(r,mean,8)

#asymmetric
asf <- function(x) max(x) - x[1] + x[2]
tr2 <- transition(r,asf,8, symm=FALSE)

#create RasterLayer objects
r1 <- raster(tr1)
r2 <- raster(tr2)
r3 <- raster(tr1, "colMeans")
```

rSPDistance

Randomized shortest path distance

Description

Calculates the randomized shortest path distance between points.

Usage

```
rSPDistance(x, from, to, theta, totalNet = "net", method = 1)
```

Arguments

x	TransitionLayer object
from	point locations coordinates (of SpatialPoints, matrix or numeric class)
to	point locations coordinates (of SpatialPoints, matrix or numeric class)
theta	theta is the degree from which the path randomly deviates from the shortest path, $0 < \theta < 20$
totalNet	total or net movements between cells
method	method 1 (as defined in Saerens et al.) or method 2 (a modified version, see below in Details)

Details

The function implements the algorithm given by Saerens et al. (2009).

Method 1 implements the method as it is. Method 2 uses $W = \exp(-\theta * \ln(P))$.

Value

distance matrix (S3 class dist or matrix)

Author(s)

Jacob van Etten

References

Saerens M., L. Yen, F. Fouss, and Y. Achbany. 2009. Randomized shortest-path problems: two related models. *Neural Computation*, 21(8):2363-2404.

[geoCorrection](#)

Examples

```
#Create a new raster and set all its values to unity.
r <- raster(nrows=18, ncols=36)
r <- setValues(r,rep(1,ncell(raster)))

#Create a Transition object from the raster
tr <- transition(r,mean,4)

#Create two sets of coordinates
sP1 <- SpatialPoints(cbind(c(65,5,-65),c(55,35,-35)))
sP2 <- SpatialPoints(cbind(c(50,15,-40),c(80,20,-5)))

#Calculate the RSP distance between the points
rSPDistance(tr, sP1, sP2, 1)
```

shortestPath

Shortest path

Description

Calculates the shortest path from an origin to a goal

Usage

```
shortestPath(x, origin, goal, ...)
```

Arguments

x	TransitionLayer object
origin	SpatialPoints, vector or matrix with coordinates, at the moment only the first cell is taken into account
goal	SpatialPoints, vector or matrix with coordinates
...	Additional argument: output

Details

As an additional argument output, the desired output object can be specified: either “TransitionLayer” (default), “TransitionStack” or “SpatialLines”.

If there is more than one path either (1) transition values in the TransitionLayer get values of 1 / number of paths or (2) the SpatialLines object will contain more than one line.

Value

Transition object

Summary-methods

Summary methods

Description

The following summary methods are available: mean, Median, max, min, range, prod, sum, any, all

Usage

```
## S4 method for signature 'TransitionStack'
Summary(x, ..., na.rm = FALSE)
```

Arguments

x	objects
...	further arguments passes to or from methods
na.rm	logical, should missing values be removed?

Value

a TransitionLayer

Note

These methods compute a summary statistic based on cell values of layers in a TransitionStack. The result of these methods is always a single TransitionLayer.

Author(s)

Jacob van Etten

Examples

```
#Create a new raster and set all its values to unity.
raster <- raster(nrows=18, ncols=36)
raster <- setValues(raster,rep(1,ncell(raster)))

#Create a Transition object from the raster
tr <- transition(raster,mean,4)

trS <- stack(tr, tr*2)

#Apply a Summary method
```

```
trSum <- sum(trS)
#plot(raster(trMean))
```

sumReciprocal	<i>Reciprocal of the sum of the reciprocals of conductance values in Transition* objects</i>
---------------	--

Description

Reciprocal of the sum of the reciprocals of conductance Transition* objects

Usage

```
sumReciprocal(x1, x2)
```

Arguments

x1	TransitionLayer object
x2	TransitionLayer object

Details

To calculate the total resistance of two resistors that are serially connected, we should add their resistance values. However, if we work with conductance values, we need to take the reciprocal of the summed reciprocals of the conductance values. This function does that when adding two TransitionLayers with conductance values (`matrixValues(tr) == "conductance"`).

For a TransitionLayer with resistance values (`matrixValues(tr) == "resistance"`), the function will not take reciprocals for that object, but will still take a reciprocal for the final product (which will consequently have conductance values).

Value

TransitionLayer object containing conductance values.

Examples

```
#Create a new raster and set all its values to unity.
raster <- raster(nrows=18, ncols=36)
raster <- setValues(raster,rep(1,ncell(raster)))

#Create TransitionLayer objects
tr1 <- transition(raster,mean,4)
tr2 <- tr1
matrixValues(tr1)

#Set one to resistance
matrixValues(tr2) <- "resistance"
```

```
#Sum the two objects
sumReciprocal(tr1,tr2)
```

transition	<i>Create an object of the class Transition</i>
------------	---

Description

Create a Transition object from a RasterLayer or RasterBrick object. Transition values are calculated with a user-defined function from the grid values.

Usage

```
transition(x, transitionFunction, directions, ...)
```

Arguments

x	RasterLayer or RasterBrick (raster package)
transitionFunction	Function to calculate transition values from grid values
directions	Directions in which cells are connected (4, 8, 16, or other), see adjacent
...	additional arguments, passed to methods

Details

Users may use one of three methods to construct a Transition* object with this function.

1) TransitionLayer from RasterLayer

```
transition(x, transitionFunction, directions, symm)
```

When a symmetric transition matrix is required, the user should supply a transitionFunction f that obeys $f(i,j) = f(j,i)$ (a commutative function).

The function transition does no commutativity check.

To obtain an asymmetric transition matrix, a non-commutative function should be supplied and an additional argument 'symm' should be set to FALSE.

2) TransitionLayer from RasterBrick

```
transition(x, transitionFunction = "mahal", directions)
```

This method serves to summarize several layers of data in a single distance measure. The distance between adjacent cells is the normalized reciprocal of the Mahalanobis distance (mean distance / (mean distance + distance ij)).

3) TransitionStack from RasterLayer

In contrast with the above methods, this method produces resistance matrices by default.

a) Continuous variables - barriers

```
transition(x, transitionFunction = "barriers", directions, symm, intervalBreaks)
```

This method creates a TransitionStack with each layer containing a discrete boundary between areas in x . Areas are defined by intervals in x . The argument `intervalBreaks` is a vector of interval breaks corresponding to the values in x . If between a pair of cells i and j , $\min(i,j) < \text{break}$ AND $\max(i,j) > \text{break}$, then the value ij in the transition matrix becomes 1.

All other values in the transition matrix remain 0. The package class `Int` offers several methods to define intervals. If `symm` is changed from the default (TRUE) to "up" or "down", it will give either only the upslope (`symm = "up"`) or downslope (`symm = "down"`) barriers.

b) Categorical variables - barriers

```
transition(x, transitionFunction = "barriers", directions)
```

In this case, areas are defined as categories in the input raster. A raster with a categorical variable can be created with `asFactor()`. The layers of the resulting TransitionStack contain all possible combinations of categories. Which layer contains the combination of categories i and j out of n categories, can be determined with these formulae:

if `symm` is TRUE: $\text{layer}(i,j) = n*(j-1) - j*(j-1)/2 + i-j$. if `symm` is FALSE and $i > j$: $\text{layer}(i,j) = ((n*(j-1) - j*(j-1)/2 + i-j) * 2) - 1$. if `symm` is FALSE and $i < j$: $\text{layer}(i,j) = (n*(j-1) - j*(j-1)/2 + i-j) * 2$.

c) Categorical variables - areas

```
transition(x, transitionFunction = "areas", directions)
```

Here, areas are also a categorical variable (see under 3b). The layers in the resulting TransitionStack represent each one area. Connections between two cells which are each inside the area are set to 1. Connections between a cell inside and a cell outside the area are set to 0.5. Connections between two cells outside the area are set to 0.

Transition-classes *Transition classes*

Description

TransitionLayer and TransitionStack (or Transition*) are the core classes of the package `gdistance`. They are the main input into the functions to calculate distances and routes. An object of the class TransitionLayer contains two main elements:

Details

a. a transition matrix with transition values between connected cells in a raster - an object of class `sparseMatrix` (package `Matrix`); b. information on the extent, resolution and projection of the underlying raster - an object of class `Raster` (package `raster`).

All slots belong to these two elements from other package, except two additional slots: 1. slot `transitionCells`, which is only used internally in the package; 2. slot `matrixValues` indicates if the nonzero values of the transition matrix contains conductance or resistance values.

Class TransitionStack contains one or more transition matrices.

Class Transition is the union of TransitionLayer and TransitionStack.

Slots

transitionMatrix Object of class "sparseMatrix"
 transitionCells Object of class "integer"
 matrixValues Object of class "character"
 ncols Object of class "integer"
 nrows Object of class "integer"
 crs Object of class "CRS" from sp package
 extent Object of class "Extent"
 layername Object of class "vector"

Objects from the Class

Objects can be created by calls of the form `new("Transition", nrows, ncols, xmin, xmax, ymin, ymax, projection)`.

Extends

Class [Raster](#)

Examples

```

showClass("TransitionLayer")

tr <- new("TransitionLayer", nrows=as.integer(36), ncols=as.integer(18),
         extent=extent(c(xmin=-180,xmax=180, ymin=-90,ymax=90)),
         crs=CRS("+proj=longlat +datum=WGS84"))

tr <- new("TransitionLayer",nrows=as.integer(36),ncols=as.integer(18),
         extent=extent(c(xmin=-180, xmax=180, ymin=-90,ymax=90)),
         crs=CRS(""))

```

Transition-extract-replace

Extracting and replacing: class Transition

Description

Methods for functions `[]` and `[<-]` for object of the class `TransitionLayer`.

Usage

```
transitionMatrix(x) <- value
```

Arguments

x an object of class Transition*
 value the value to assign

Details

Methods for functions `[[` and `[[<-` for object of the class TransitionStack.

Also see [adjacencyFromTransition](#).

Examples

```
#Create a new raster and set all its values to unity.
r <- raster(nrows=18, ncols=36)
r <- setValues(r,rep(1,ncell(r)))

#Create TransitionLayer objects
tr1 <- transition(r,mean,4)
tr2 <- tr1

#Extracting and replacing
tr1[cbind(1:9,1:9)] <- tr2[cbind(1:9,1:9)]
tr1[1:9,1:9] <- tr2[1:9,1:9]
tr1[1:5,1:5]
```

Transition-slots *Extract or change elements of Transition* objects*

Description

These functions are to be used to access slots of Transition* objects.

Usage

```
transitionMatrix(x, inflate)
```

Arguments

x object of class Transition*
 inflate logical (default is TRUE)
